I chose option B, using Hugging Face/flan-t5-base for this project, to generate short descriptions from product names and the keywords. I used Flask to connect the model to a simple web interface where user can enter the product's name and keywords and then submit the form to see the description about the product created by the model. One challenge I faced was my first model, GPT-2, produced irrelevant or repetitive text. Therefore, I switched to FLAN-T5 because it follows instructions more appropriately and creates finer descriptions for this project, although its output can still be basic and may not include every keywords consistently.

The project can be improved by testing different products, checking whether the generated descriptions use the requested keywords, and allowing human to review the text before publication. In a real retail, this model can help to fasten the description content and maintain consistent format, but human-in-a-loop is always a must before publishing. The model might invent or imply product features, omit important details, or produce misleading claims. Retailers should verify descriptions against reliable product information, protect any customer or business data entered into the system, and make sure the final copy is accurate and fair to customers. Another improvement would be to add a multilingual description generator. The application could translate product descriptions into different languages, allowing retailers to reach customers from different cultural and language backgrounds.
